Transients in Power Systems A transient phenomenon in any type of system can be caused by a change of the operating conditions or of the system configuration. Power system transients can be caused by faults, switching operations, lightning strokes or load variations.

Introduction to Transient Analysis of Power Systems

Applications in power system transients such as identification, storage, and propagation analysis of transients will then be discussed and the conclusions made. The earliest recorded development of wavelet functions appears to be in the area of physics.

What are Transients & How to eliminate them from Power System?

Electrical transients are momentary bursts of energy induced upon power, data, or communication lines. They are characterized by extremely high voltages that drive tremendous amounts of current into an electrical circuit for a few millionths, up to a few thousandths, of a second. Large transients on the power system originating outside of a facility are best initially diverted at the service entrance of a facility.

A transient event is a short-lived burst of energy in a system caused by a sudden change of state. The source of the transient energy may be an internal event or a nearby event. The energy then couples to other parts of the system, typically appearing as a short burst of oscillation.
